1.0 SUMMARY

The DAC Deposit (the Project) is located in northwestern Quebec, in a region well known for prolific gold production. Numerous historical and current operating mines are located to the south of the Project. In 2009, Quebec was the second largest gold producer in Canada and the tenth largest producer in the world. The region is host to several significantly large lode-gold deposits, with a historical production of over 45 million ounces (oz) of gold (Au). The DAC deposit is one of three significant gold zones on the Destiny property.

The property is located in the Despinassy Township, approximately 75 kilometres (km) north-northeast of Val d'Or, Quebec, at the corner of four NTS sheets: 32C/11, 32C/12, 32C/13 and 32C/14. The approximate coordinates for the center of the property are longitude 77° 28' and latitude 48° 44' or UTM coordinates 319025E and 5401228N, in Zone 18, NAD 83.

In November 2010, Wardrop Engineering Inc. (Wardrop) was commissioned by Alto Ventures Ltd. (Alto) on behalf of Alto and their joint venture partner Pacific North West Capital Corp. (PFN) to complete a resource estimate and technical report on the project based on having completed 38 new diamond drillholes on the property since 2008. This report is to comply with disclosure and reporting requirements set forth in National Instrument 43-101 (NI 43-101) Standards of disclosure for Mineral Projects, Companion Policy 43-101CP to NI 43-101, and Form 43-101F of NI 43-101.

The property consists of 175 contiguous claims (surveyed 40 hectare (ha) lots), covering an area of approximately 7,421 ha, held 100% by Alto. The project is currently under an option agreement with PFN, whereby PFN can earn a 60% interest in the project by funding exploration and making required payments.

1.1 GEOLOGY

The property is located within the Amos-Barraute section of the southeastern portion of the Abitibi Greenstone Belt. Most of the property is underlain by metavolcanic rocks of the Amos Group (Lower Amos Formation), characterized by tholeiitic basalts intruded by thick ultramafic and gabbro sills. The southern limit of the property is underlain by rocks of the Harricana Group (Upper Figuery Formation) comprising porphyritic andesite, volcanoclastic turbidite, conglomerate, iron formation, dacite and rhyolite.

Most of the property is interpreted to be underlain by strongly foliated mafic volcanics, interbedded with minor amounts of siltstone, graphitic mudstone and sulphide iron formation. In drill core, the mafic volcanic rocks are very fine grained

and composed mainly of chlorite and amphibole with minor feldspar. They are variably altered to carbonate (mainly calcite), biotite, sericite and/or silica-rich bands, generally less than 1 centimetre (cm) wide and accompanied by disseminated pyrite, pyrrhotite, with minor sphalerite, galena and chalcopyrite. Epidote alteration and garnetiferous bands are also observed locally.

The DAC Deposit contains mineralization that is analogous to the shear-hosted quartz-carbonate vein lode gold typical to the Abitibi Belt of eastern Ontario and western Quebec. Two distinct alteration and mineralization events were observed:

1. an early phyllosilicate-calcite-sulphide-silica event, and;
2. a younger superimposed base metal-bearing auriferous milky white quartz veining event.

The first event is associated with anomalous (>100 parts per billion (ppb) Au) to low grade gold concentration (<5 grams per tonne (g/t) Au) and consists of fine grained brown biotite and grey-buff carbonate (mainly calcite with minor ferrodolomite-ankerite) and local weak to strong yellow sericite alteration. The alteration is concentrated in bands, generally 1 to 2 cm wide. Grey, boudinaged calcite-quartz veins/veinlets occur locally; trace to 20% disseminated and vein type pyrite, pyrrhotite and minor light brown to reddish sphalerite are also present in these altered zones.

The second mineralizing event is characterized by younger quartz veins and veinlet stockwork, generally less than 1 metre (m) wide, but up about 10 m wide. These veins crosscut the earlier mineralization and the S1 foliation, but are boudinaged and broadly folded along the S2 foliation (late syn-kinematic). These veins contain generally higher-grade gold mineralization than the phyllosilicate event, commonly grading more than 5 g/t Au, up to 178.5 g/t Au.

Extensive exploration has been conducted at DAC by various operators in the past, primarily Cameco and Alto. Due to the lack of outcrop in the region, geophysics and diamond drilling are the primary sources of geological information.

1.2 CONCLUSIONS

The Destiny Property comprises a land package with a strike-length of over 12.5 km along the Despinassy Shear Zone, western Quebec. The Despinassy Shear is an under explored shear located in a region known to host significantly large lode-gold deposits. The geological dataset generated by Alto consisting of data derived from diamond drilling is deemed to be suitable to support geological interpretation and resource estimation.

The DAC mineral resources were developed on five parallel gold bearing zones at a gold cut-off grade of 0.5 g/t Au, and the five zones contain an Indicated Resource of

about 10.8 million tonnes with an average grade of 1.05 g/t gold. The Inferred Resource totals 8.3 million tonnes with an average grade 0.92 g/t gold.

1.3 RECOMMENDATIONS

Exploration on the Project is proposed as two separate programs, which are independent of each other and can be run concurrently, as the result of one program does not affect the work proposed in the second program.

1.3.1 PHASE 1 DAC RESOURCE EXPANSION

Phase 1 is designed to investigate the strike extension of the current resource for Zones 1, 2, 3, 4 and 5. This will entail a diamond drilling program.

The drilling campaigns should be designed to target the potential strike extensions of Zones 1 to 5 to a depth of approximately 450 m vertical. Some holes will have to be collared in to Zone 1 in order to intersect Zone 5 at a shallow depth.

The proposed budget for Phase 1 is \$1.0 million.

1.3.2 PHASE 2 DAC RESOURCE DELINEATION

Phase 2 is designed to investigate the known resource in order to improve the understanding of the geometry and potentially increase the resource category of all five zones. The Phase 2 program does not depend on the successful results from the Phase 1 program.

Drilling should target all zones on an approximate grid of 20 m along strike and 15 m down dip.

The proposed budget for Phase 2 is \$3.1 million.

2.0 INTRODUCTION

The Project is located in northwestern Quebec, approximately 75 km from Val d'Or and is currently owned by Alto.

In November 2010, Wardrop was commissioned by Alto on behalf of Alto and their joint venture partner PFN to complete a resource estimate and technical report on the project based on having completed 38 new diamond drillholes on the property since 2008.

The object of the report is to:

- compile historical work and activities on the property
- generate a resource estimate on the DAC deposit
- complete a Technical Report on the Project including summarizing all land tenures, exploration history, drilling, and resource estimates
- provide recommendations and budget for additional work on the Project.

This report has been compiled in accordance with NI 43-101, Form 43-101F1, and Companion Policy 43-101CP.

All the data files that were reviewed for the report were provided by Alto in digital format, and access to paper reports and logs was granted when requested. Alto made its own work available, and compiled historical work conducted by previous operators on the Project.

The primary author of this report is Mr. Todd McCracken, P. Geo., who is a Professional Geologist with 19 years of experience in exploration and operations, including several years working in shear-hosted lode gold deposits. Mr. McCracken visited the Project between November 2 and 3, 2010 inclusive.

3.0 RELIANCE ON OTHER EXPERTS

Wardrop has reviewed and analyzed data and reports provided by Alto, together with publicly available data, and have drawn its own conclusions, augmented by its direct field examination.

Wardrop is relying on reports, opinions and statements from experts who are not qualified persons for information concerning legal, environmental, political or other issues and factors relevant to the technical report.

Information from third party sources are quoted in the report or referenced. Neither Wardrop or the author of this report are qualified to provide extensive comment on legal issues, including status of tenure associated with the DAC Project referred to in this report. A description of the property and ownership is provided for general information purpose only. Assessment of these aspects has relied on information provided by Alto, which has not been independently verified by Wardrop.

4.0 PROPERTY DESCRIPTION AND LOCATION

The Destiny property is located in the Despinassy Township, approximately 75 kilometres north-northeast of Val d'Or, Quebec (Figure 4-1). From Val d'Or, it can be reached by travelling a total of 85 kilometres, via paved provincial highway 397 northward and then eastward to the village of Rochebaucourt; then on a gravel road northward and then eastward to the property. This road, along with a number of ATV trails, provides good access to the southern half of the property. The northern and western portions of the property are easily accessible by following the highway further northward to the village of Despinassy and turning westward onto the gravel road which separates ranges III and IV. A newly constructed all-season forestry road branches south-westward from this range road and provides good access to the area lying north of the DAC Zone. Construction of another forestry road is also planned southwest of the small lake which lies along road 397, as it turns southward to the village of Rochebaucourt.

Figure 4.1 Location Map

The Destiny block of claims is situated in the south-central portion of Despinassy Township as well as a few claims in vassal and Rochebaucourt townships. The property occurs at the corner of four NTS map sheets 32C/11, 32C/12, 32C/13 and 32C/14. The approximate coordinates for the center of the property are longitude 77° 28' and latitude 48° 44' or UTM coordinates 319000E and 5401000N, in Zone 18,

NAD 27. The property consists of 175 contiguous claims (Table 4.1), covering an area of approximately 7,421 ha. Claim numbers are shown in Figure 4.2.

Note: updated October 8, 2010

Underlying Royalties

A* Original Despinassy Claims

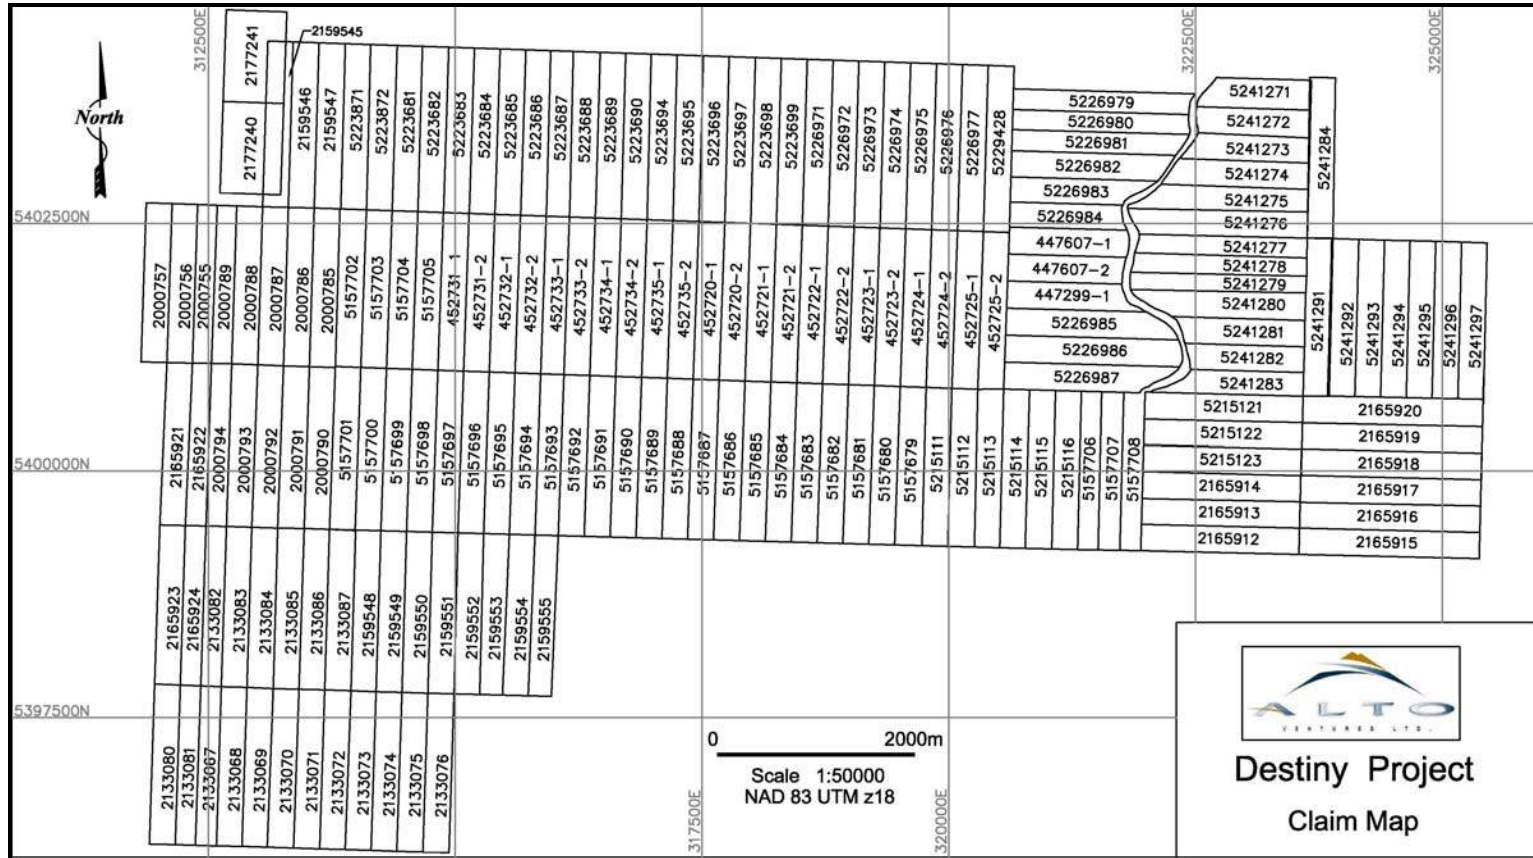

- (1) 1% Net Smelter Return (NSR) to Umex Inc.
- (2) and additional 1.5% NSR capped at \$500,000
- (3) 1% NSR to Commander Resources with a buy back of 0.5% NSR for \$500,000

B* Rochebaucourt Claims optioned from Battle Mountain

- (1) 3% NSR payable to Battle Mountain (now Franco Nevada) with the option to reduce to 2% NSR by paying Franco \$1,000,000
- (2) 0.25% NSR payable to Commander Resources

C* Cameco staked claims under Cameco-Commander Joint Venture are subject to 1% NSR payable to Commander Resources, with a buy back of one half (0.5%) of Commander's royalty for \$500,000

Figure 4.2 Claim Map

The project is an option agreement joint venture between Alto and PFN. PFN is funding exploration to earn into the project and Alto is the manager of the project. The property is made up of public and private lands. The names and addresses of the private lot owners are available from the Municipalité Régionale de Comté (MRC) in Amos. The public lots are managed by the Quebec Ministry of Resources Naturelles et Fauneis.

The original Despinassy Property (25 claim units) is encumbered by a 1% NSR royalty payable to Umex Inc. and an additional 1.5% NSR, which is capped at \$500,000 payable also to Umex Inc. The claims are also encumbered by a 1% NSR royalty payable to Commander Resources with the option to reduce the NSR to 0.5% for \$500,000

The Rochebaucourt Property (30 claim units) is encumbered by a 3% NSR to Franco-Nevada with the option to reduce the NSR by 1% to 2% by paying Battle Mountain Canada Ltd. \$1,000,000. Commander Resources retains a royalty of 0.25% NSR.

Fifty-eight "Cameco" claims were acquired by staking under the Cameco-Commander Joint Venture and are subject to the following NSR royalties payable: (1) 1% to Commander Resources with a buy back of one half of the royalty (0.5%) for \$500,000.

The Destiny Gold Property is under option to PFN under a Letter to Option Agreement dated August 14, 2009. Under the terms of the Option Agreement, PFN will pay Alto \$200,000 in cash, provide Alto with 250,000 common shares of PFN, and complete a total of \$3,500,000 in exploration expenditures over a four year period to earn a 60% interest in the Destiny Gold Property. Subsequent to vesting of its interest, PFN will form a joint venture with Alto to further develop the project as set forth below.

(i) Cash Payments:

\$25,000 on Board of Directors and regulatory approvals
\$25,000 on 1st Anniversary of the Agreement
\$50,000 on 2nd Anniversary of the Agreement
\$50,000 on 3rd Anniversary of the Agreement
\$50,000 on 4th Anniversary of the Agreement

(ii) Share Payments:

25,000 PFN shares on Board of Directors and regulatory approvals
50,000 PFN shares on 1st Anniversary of the Agreement
75,000 PFN shares on 2nd Anniversary of the Agreement
100,000 PFN shares on 3rd Anniversary of the Agreement

(iii) Exploration Expenditures

PFN shall complete a cumulative total of \$3,500,000 in Exploration Expenditures over the Option period, with minimum expenditures as follows:

\$300,000 in Exploration Expenditures in Year 1 of the Agreement
\$300,000 in Exploration Expenditures in Year 2 of the Agreement
\$400,000 in Exploration Expenditures Year 3 of the Agreement
\$400,000 in Exploration Expenditures Year 4 of the Agreement

The Option is currently in good standing.

There are no known environmental impacts affecting the Despinassy Property at this time.

5.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

5.1 SITE TOPOGRAPHY, ELEVATION AND VEGETATION

In the area of the DAC Zone and its east and western extensions, the terrain is flat, humid and poorly drained, with no known bedrock exposures. Vegetation consists of alternating alder-covered humid areas with sparse poplar and spruce growth and heavily wooded areas, with mature stands of poplar, spruce, and fir. Maximum relief rarely exceeds 5 to 10 m and is mostly limited to creek valleys. Overburden mainly consists of a thick mantle of clay, which varies in thickness throughout the property.

Locally, few 5 to 6 m topographic highs (mounds or dunes) are composed of sandy till or sand. The overburden thickness averages 15 m and thins northward to 10 m. In the area drilled to the west, it ranges 6 to 12 m, with one exception where it exceeded 30 m. In the area drilled to the east, it ranges 6 to 20 m.

5.2 ACCESS

In terms of access to heavy drill equipment, the DAC Deposit lies partly on private lots and in locally wet and poorly drained terrain, best drilled during the winter months. The areas to the east and west of the DAC Deposit remain accessible for summer drilling operations, as does the area to the north, where drill collars for future deep drilling on this zone would be located. This area is easily accessible via the newly constructed forestry road.

5.3 CLIMATE

There is no active weather station at the village of Despinassy. The climate in the region is typical Canadian Shield summers and winter with temperatures averaging from 14 degrees Celsius (°C) in the summer to -15°C in the winter. Precipitation comes in the form of 50 to 60 cm of snow in the winter months and 90 to 100 millimetres (mm) of rain in the summer.

5.4 INFRASTRUCTURE

The property benefits from a number of hydroelectric power lines. A major line crosses the property south-westward just east of the DAC Zone and another line lies along provincial road # 397, only 800 m to the south. This line veers northward along this road in the eastern part of the property. Another line lies along the range road separating ranges III and IV.

Finally, general and skilled labour is readily available from Val d'Or, Lebel-sur-Quévillon and Amos, whereas mining and exploration manpower, services and equipment are available in Val d'Or.

6.0 HISTORY

The exploration history of the DAC project dates back to the 1930's. Table 6.1 summarizes the history of the property and highlights some of the results.

Table 6.1 DAC History

Year	Company	Program	Results
1934	Quebec Bureau of Mines	Geological mapping	Map 313 1:63,360 scale map

2006	Alto	19 diamond drillholes (NQ) totaling 5,106 m	14.3 g/t over 2.1 m 19.5 g/t over 0.7 m 13.2 g/t over 1.0 m
2007	Alto	NI 43-101 technical report and resource estimation	
2008	Alto	VTEM airborne survey for a total of 982 line km 17 diamond drill holes (NQ) totaling 4,333 m targeted the Darla Zone, Zone 20 and Zone 21	
2009	Alto/PFN	Phase- domain Induced Polarization (IP) ground survey totaling 17.9 line km	
2009-2010	Alto/PFN	19 diamond drillholes (NQ) totaling 7,628 m of which 16 hole targeted the DAC Deposit	see section 11.0

A resource estimate was complete in January 2007 by W.A Hubacheck Consultants Ltd. The methodology and results are described in Section 17.1.

7.0 GEOLOGICAL SETTING

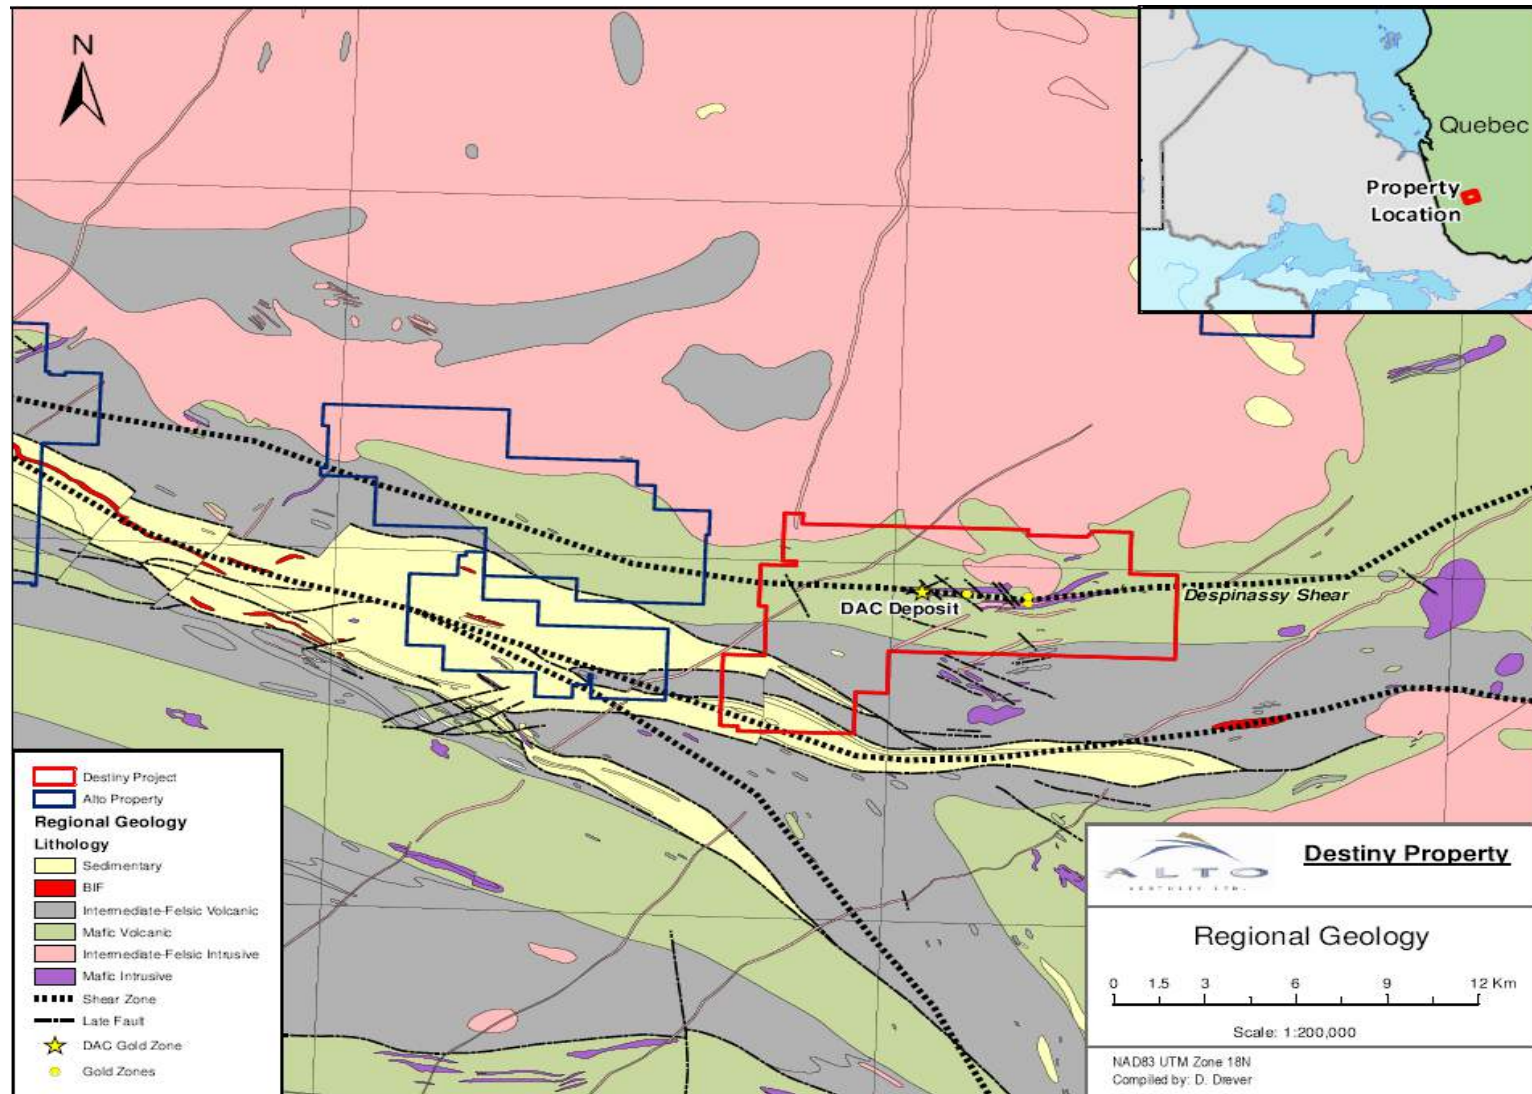

7.1 REGIONAL GEOLOGY

The property is located within the Amos-Barraute section of the southeastern portion of the Abitibi Greenstone Belt. According to Otis and Beland (1986), most of the property is underlain by metavolcanic rocks of the Amos Group (Lower Amos Formation), characterized by tholeiitic basalts intruded by thick ultramafic and gabbro sills. The southern limit of the property is underlain by rocks of the Harricana Group (Upper Figuery Formation) comprising porphyritic andesite, volcanoclastic turbidite, conglomerate, iron formation, dacite and rhyolite (Figure 7.1).

The metavolcanic rocks in Despinassy Township have been affected by two deformation events. The first one is interpreted to coincide with the Kenoran orogeny and is responsible for the formation of regional scale folds. The axial trace of a regional anticline (Ducros anticline) passes just south of the property. The anticline is characterized by an overturned axial plane oriented ESE, dipping steeply to the north, with a fold axis plunging 30E to 50E to the west. The large granitic batholith (Bernetz), found at the northern limit of the property, is interpreted to have been emplaced during this tectonic event. The second deformation event is related to the intrusion of the Montgay batholith, located to the southeast of the project area. It is responsible for the deviation to the NNW-SSE of the axial trace of the regional folds. Both the Bernetz and the Montgay batholiths upgraded the regional greenschist facies metamorphism to lower amphibolite facies within 5 km of their contacts. Late NNE and NE faults crosscut all lithologies, except the diabase dykes emplaced along the NE faults.

Regional structural measurements were taken from a series of outcrops along the Laflamme River, about 1.5 km south of the Despinassy property. The strong foliation observed regionally in the altered mafic metavolcanics is interpreted to reflect a composite between an earlier S1 foliation, transposed parallel to a later S2 foliation. The mean orientation of the composite S1/S2 is 257E/70E and it is associated with an interpreted regional stretching lineation oriented at 350E/51E.

Figure 7.1 Regional Geology

7.2 PROPERTY GEOLOGY

The geological map of the property (figure 7.2) was constructed by compiling available airborne and ground magnetometer surveys data, IP and Resistivity and HLEM data and combining these geophysical data sets with diamond drill hole information and the very few outcrops found near the Laflamme River and at the northwest corner of the property. The descriptions of the geology provided below are limited mainly to the centre of the property, where most of the drilling has been carried out to date.

Most of the property is interpreted to be underlain by strongly foliated mafic volcanics, interbedded with minor amounts of siltstone, graphitic mudstone and sulphide iron formation (good H.L.E.M. conductors and strong I.P. anomalies). In drill core, the mafic volcanic rocks are very fine grained and composed mainly of chlorite and amphibole with minor feldspar. They are variably altered to carbonate (mainly calcite), biotite, sericite and/or silica-rich bands, generally less than one centimetre wide and accompanied by disseminated pyrite, pyrrhotite, with minor sphalerite, galena and chalcopyrite. Epidote alteration and garnetiferous bands are also observed locally. Historically, these rocks were referred to as mafic to intermediate tuff, but in most cases, they are deformed and altered mafic flows and sills. One of the mafic horizons is distinctively amygdaloidal and has been traced in drill core from line 2+00E to 6+00W, between the two marker quartz-eye melanogabbros. Well developed pillowed and tuffaceous textures were observed only in relatively undeformed mafic lithologies intersected to the south of the interpreted deformation corridor.

The mafic metavolcanic rocks are also intruded by a suite of syn-volcanic mafic sills composed of three separate end members: amphibole-phyric gabbro (referred to as amphibolitized mafic volcanics or gabbro), leucocratic magnesium-rich gabbro (referred to as leucogabbro) and melanocratic, iron-rich, quartz-phyric gabbro (referred to as quartz-eye mafic or melanogabbro). Since the contacts between these three facies are relatively clear in drill core, they are mapped as separate geological units, even if they may belong to the same intrusive suite. All units are very variable in texture and exhibit medium to coarse grained, equigranular to porphyritic/porphyroblastic, massive to weakly foliated sections, interlayered with finer grained strongly foliated horizons. The amphibole-phyric phase has never been observed to date in contact with the leucogabbroic phase, but only in contact with the quartz-eye melanogabbroic phase.

The amphibole-phyric phase usually contains trace to 40% diffuse amphibole phenocrysts/porphyroblasts (up to 1 cm long), associated with minor feldspar laths and biotite specks, with a very fine grained chloritic matrix. It is mainly found at the northern contact of the quartz-eye melanogabbroic phase in contact with aphyric mafic volcanics or as minor sills/dykes intruding the mafic flows. The gabbro units are generally more massive than the aphyric mafic rock, although they are often strongly deformed, mainly near the contacts with the flows. Very little biotite or

sericite alteration is seen in these amphibole-phyric horizons. The intrusive nature of these amphibole phyric horizons is suggested by their close association with the quartz-eye melanogabbro sills (which are clearly intrusive in nature).

The leucocratic gabbro is composed of 10 to 50% white plagioclase laths (1 to 5 mm long), 5 to 20% amphibole and/or biotite (1 to 3 mm in size) and 30 to 50% chloritic matrix. Very rare blue to grey interstitial quartz grains are found locally. The leucogabbro and amphibole phyric gabbro are strongly deformed and altered in several holes. However, no significant gold assays were obtained from these two gabbroic phases, in contrast with the numerous gold enriched intersections found in the melanocratic phase. This difference in gold content between the quartz-eye melanogabbro and the other phases could be explained by the more iron-rich melanocratic facies being a better chemical trap for gold.

The melanocratic, quartz bearing, gabbro is considered as a good marker horizon on the property because it is easily traced on surface by its highly magnetic signature, and forms three subparallel east trending bands crossing the centre of the property. This unit contains up to 35% plagioclase laths (less than 1 mm long) in a matrix composed of amphibole, biotite, chlorite and locally, up to 10% magnetite specks. Light blue, fine to medium grained quartz grains or “eyes” occur throughout the unit, in amounts generally ranging from trace to 1%, but locally up to 10%. An anticlinal fold nose linking the two southernmost quartz gabbro layers has been interpreted from the ground magnetometer survey around line 1+00S, between lines 6+00W and 10+00W. The fold-nose interpretation is supported by the structural data measured in drill core (Babin, 2000). The gabbro sills have been cut by northwest and northeast trending cross faults and some of the northeast trending magnetic breaks may also correspond to late diabase dykes.

The mafic volcanics and the gabbroic sills are intruded by numerous feldspar porphyritic, quartz porphyritic and quartz-feldspar porphyritic dykes and sills, often concentrated along geological contacts (flow or intrusive contacts). Before 1999, these foliated dykes, variably altered by sericite, silica and carbonate development, were referred to as felsic tuff. Their thickness varies generally between 10 cm and 10 m, with an average thickness of about 1 m and their contacts are oriented parallel to sub-parallel to the foliation. The porphyry units are weakly to intensely foliated and make up to 30% of the mafic sequence locally. Quartz and plagioclase phenocryst content is very variable, but is generally between 1% and 25% (average of about 10%). Phenocrysts are generally less than 5 mm across and float in an aphyric and moderately siliceous matrix. The least altered and deformed dykes often contain up to 5% disseminated biotite specks, less than 1 mm in size.

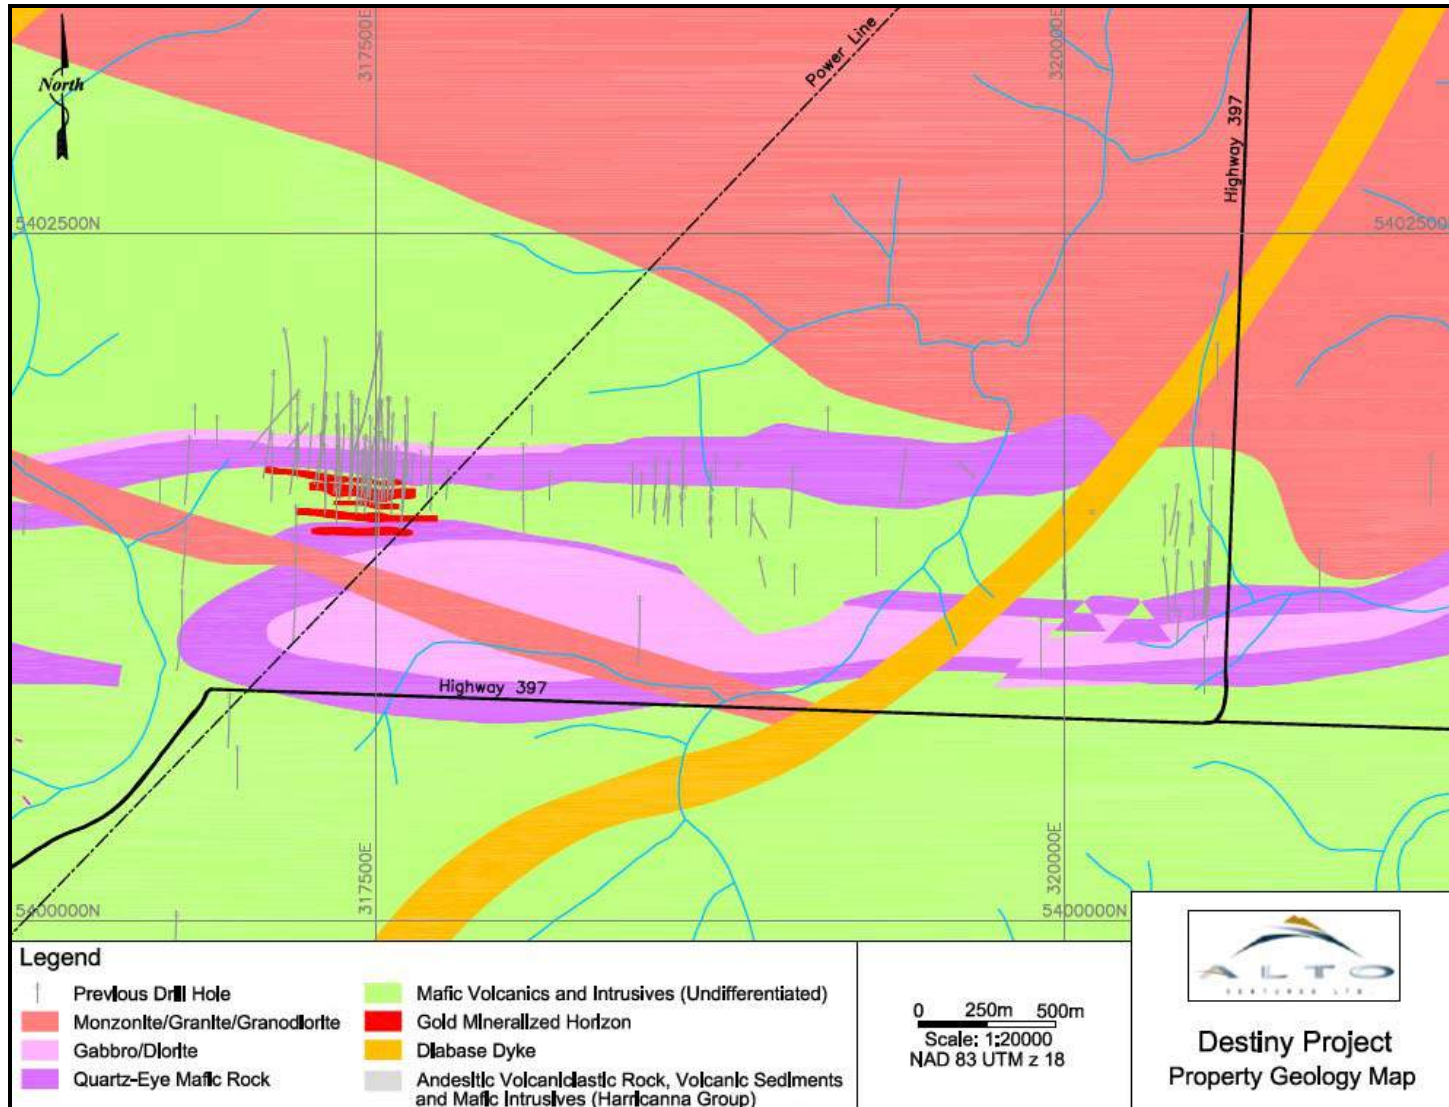

Hole DES99-27, located at the southwest of the property, intersected a 70 m thick sequence of intermediate volcanoclastic turbidite composed of interbedded conglomerate, sandstone and mudstone. Stratigraphic tops from load and erosion features observed in the core are interpreted to be to the south. It is capped by andesitic and gabbroic sills/flows to the end of the hole. This andesitic and

volcaniclastic sequence is unique on the property and is interpreted to be part of the Upper Figuery Formation as described by Otis and Béland (1986).

The lower part of hole DES00-54, located in the northwest corner of the property, intersected dacitic to rhyodacitic rocks, possibly fragmental in nature. The unit is siliceous, moderately to strongly foliated and displays variable sericitic stringers and ghostly bands which may represent flattened and preferentially sericitized felsic fragments (lapilli-size). Rare disseminated feldspar and quartz phenocrysts (less than 5 mm long) are observed generally within the apparent clasts. Fine grained biotite is also seen locally in the more homogeneous horizons. This sequence is very similar to the Upper Amos Formation and could represent part of a felsic volcanic center.

A series of granitic intrusions (dykes, sills and plugs), interpreted to be related to the Bernetz batholith, intrudes the lithologies in the northeast part of the property. The granitic rocks contain up to 5% disseminated magnetite and consequently exhibit a strong magnetic susceptibility. A late monzonitic to granodioritic dyke swarm oriented NW-SE was encountered in drilling in the southwest corner of the property and crosscuts all lithologies there. The dyke swarm is approximately 150 metres thick and more than 3 km long. It is represented by a low magnetic signature on the ground magnetometer survey. The dyke contacts are very irregular and often brecciated. The relation of this dyke swarm to the Bernetz batholith is not known.

Figure 7.2 Property Geology

7.3 STRUCTURAL GEOLOGY

The area was subjected to at least two deformation events. The early biotite-sericite-calcite-sulphide alteration, the calcite-quartz veinlets and the felsic dykes are interpreted to have been overprinted and transposed by a strongly penetrative S1 foliation (orientation unknown), developed during the first deformation event. Therefore, the main alteration would have been emplaced pre- to syn-D1 deformation. Subsequently, the alteration, the felsic dykes and S1 were folded around younger S2 axial plane cleavages, developed during D2 event. The general orientation of the S2 cleavage (axial plane of folds) measured in drill core is 263°/62° and it is showing a strong mineral lineation along cleavage surfaces oriented at 310°/40°. Small-scale folds measured in drill core are estimated to plunge at 280°/20°.

Foliation intensity appears to be directly related to the degree of early phyllosilicate alteration with the strongest alteration associated with the felsic dykes and their immediate wall rocks. The absence of well-developed kinematic indicators such as S-C, extensional crenulation cleavage or shear bands (C'), Riedel and Riedel' shears, or widespread asymmetric augen structures suggests the intense penetrative fabric probably did not develop in response to non-coaxial simple shear. The strong foliation development is interpreted to largely represent non-rotational or pure shear flattening about a broadly north-south axis of principal shortening (σ_1). However, the presence of zones or intervals of more intense penetrative 'shear' fabric, locally with minor rotational components, reflects heterogeneous strain due to local anisotropy and rheological contrasts, notably between altered and unaltered lithologies and near the contacts of dykes. These local shears are often better developed along the overturned upper limbs of D2 folds. Auriferous and base metal-bearing milky white quartz veins are provisionally interpreted as late syntectonic tension and shear type veins related to the development of these local shears and the S2 foliation during D2.

Based on vergence indicators, it would appear that the drill holes examined intersect the overturned upper limb (e.g. north-dipping) of a larger macroscopic synform, whereas the lower portions of the drill holes appear to intersect the hinge zone of this synform. The relatively wider intersections noted for Zone 3 possibly reflects structural thickening of the alteration and mineralization in the fold hinge of this inferred synform. The reversal in structural facing directions below Zone 3 indicates the presence of a larger antiformal structure to the south of the area examined (as proposed also by the ground magnetic survey).

8.0 DEPOSIT TYPE

The deposit model used at DAC is analogous to the shear-hosted quartz-carbonate vein lode gold typical to the Abitibi Belt of eastern Ontario and western Quebec. As with all deposits, there are variations within the deposits model.

Anomalous to sub-economic gold mineralization occurs in two wide gold-bearing shears lying along or close to the north and south boundary of the mafic volcanic assemblage. These shears have been invaded by quartz-porphyritic felsic intrusive sills and display very strong mylonitic deformation, biotite and sericitic (potassic) alteration and locally, silica alteration. This unit is flanked both to the north and south by a gabbroic unit characterized by locally abundant blue quartz eyes. Shears locally hosting very high-grade gold mineralization also occur within the southern gabbroic unit and lie parallel to the main gold-bearing shears in the volcanic unit.

The most extensive and higher grading gold mineralization occurs where two shear zones and their felsic intrusives are strongly folded, brecciated and quartz flooded. There is evidence in the drill core to support the theory that the shear zones are part of a large “Z” fold structure, some 150 m in amplitude. This fold structure is host to four broad zones of meter to decimetre thick mineralized shearing, in what has been described as the DAC Zone.

The most extensive and strong gold mineralization occurs in the central portion of the proposed fold, in the shear zone designated Zone 2, along what appears to be faulting and brecciation associated with the axial plane of the large fold. This zone also comprises the most extensive intersections of felsic intrusives, which were cored over intervals ranging to 15 to 20 m. The intrusives display the strong brecciation and quartz flooding.

Gold appears to be directly linked to this quartz and occurs primarily in the native state.

9.0 MINERALIZATION

9.1 ALTERATION AND MINERALIZATION

Anomalous gold assays (>100 ppb) associated with variably altered and deformed zones have been intersected within a corridor extending for more than 4 km in length, and about 1.1 km wide. This corridor has been tested by sporadic drilling over its length and locally to below 670 vertical depth.

More detailed drilling has been focused in the area between lines 1+00W and 7+00W and two distinct alteration and mineralization events were observed: (1)- an early phyllosilicate-calcite-sulphide-silica event, and (2)- a younger superimposed base metal-bearing auriferous milky white quartz veining event. The first event is associated with anomalous (>100 ppb Au) to low-grade gold concentration (<5 g/t Au) and consists of fine grained brown biotite and grey-buff carbonate (mainly calcite with minor ferro-dolomite-ankerite) and local weak to strong yellow sericite alteration. The alteration is concentrated in bands, generally 1 to 2 cm wide. Grey, boudinaged calcite-quartz veins/veinlets occur locally; trace to 20% disseminated and vein type pyrite, pyrrhotite and minor light brown to reddish sphalerite are also present in these altered zones.

The type (1) mineralization appears to be genetically related to the emplacement of the felsic porphyry dykes. The altered mineralized zones are generally centered on the felsic dykes and the alteration is commonly more intense and wider at the footwall of those dykes. The width and the intensity of the alteration were observed to be proportional to the abundance and width of the felsic dykes. The alteration of the wall rock displays a strong asymmetric zonal distribution from the dyke contacts outward. Sericite development, pervasive biotite and calcite alteration, grey calcite-quartz veins/veinlets and disseminated pyrite (with minor pyrrhotite and sphalerite) are more abundant near the dyke contacts. Moving away from the dyke, the sericite alteration and the amount of calcite-quartz veining decrease rapidly, the biotite-calcite alteration becomes concentrated in 1 to 2 cm thick layers, and the percentage of sulphides decreases gradually. The ratio of pyrrhotite to pyrite is usually increasing outward from the felsic dyke contacts. Further away from the dyke contacts, the biotite and sulphides gradually disappear and only the banded calcite alteration is left as the most distal alteration facies. Gold grades decrease gradually from the dyke contacts outward and generally no anomalous gold assays are found without the presence of biotite or sericite in the host rock.

The second mineralizing event is characterized by younger quartz veins and veinlet stockwork, generally less than 1 m wide, but up about 10 m wide. These veins crosscut the earlier mineralization and the S1 foliation, but are boudinaged and

broadly folded along the S2 foliation (late syn-kinematic). These veins contain generally higher grade gold mineralization than the phyllosilicate event, commonly grading more than 5 g/t Au, up to 178.5 g/t Au over 1.0 m (in hole DES06-85). Disseminated to stringer pyrite is always present in the auriferous veins along with variable amounts of pyrrhotite sphalerite, galena, chalcopyrite and visible gold. It was observed that the veins, which contain visible gold, galena and Sphalerite, returned the highest gold assays. It should be noted, however, that minor amounts of sphalerite are common, but many veins containing sphalerite did not return significant gold assays. Galena appears to be a better indicator mineral.

The coarseness of the sulphides and the higher gold concentration in the milky white veins may indicate remobilization and concentration of pre-existing metals associated with the earlier event. Vein development along specific dyke margins can rarely be correlated over more than 50 m strike length between drill fences, thereby suggesting they are relatively small and discontinuous at the depth currently tested.

The presence of early phyllosilicate alteration, and associated anomalous gold assays, were used to define the mineralized zones (termed Zone 1 through 5) identified in the drill hole cross sections. Since all the zones are alike and appear to follow lithological contacts, the correlation between the different zones from section to section was made using stratigraphy.

For example, the altered mineralized zone between the northern melanogabbro and the marker amygdaloidal flow was correlated as Zone 1. The zone at the lower contact of that flow was correlated as Zone 2 (not always present). The alteration zone at the contact of the mafic volcanics and the lower melanogabbro was termed Zone 3 and the zone within the melanogabbro was named Zone 4. Zone 5 is located entirely within the melanogabbro below Zone 4. All these zones were first established from the stratigraphy. Each zone is generally defined by the presence of abundant quartz veining (>25%), mainly the milky white auriferous quartz vein type. Since these veins appear to be discontinuous over more than 50 m along strike, the correlation of these quartz veining zones between sections is still very speculative.

9.2 ZONE 1

Zone 1 is located as the hanging wall zone of the DAC deposit. It has been delineated by diamond drilling and is currently approximately 520 m in strike by 500 m vertical depth or 580 m down dip. The zone has an average true width of 16 m with a dip of approximately -60° to the north. The zone occurs within the metavolcanics at or near the contact with the northern gabbro.

Figure 9.1 Zone 1 Oblique Long Section (not to scale)

9.3 ZONE 2

Zone 2 is located approximately 8 to 10 m beneath (footwall) to Zone 1. It has been delineated by diamond drilling and is currently approximately 450 m in strike by 580 m vertical depth or 620 m down dip. The zone has an average true width of 30 m with a dip of approximately -60° to the north. The zone is the thickest zone in the deposit.

Figure 9.2 Zone 2 Oblique Long Section (not to scale)

9.4 ZONE 3

Zone 3 is the smallest zone within the DAC deposit and is located approximately 25 m underneath Zone 2 and immediately above Zone 4. At times, Zones 3 and 4 may actually merge into a single zone. It has been delineated by diamond drilling and is currently approximately 380 m in strike by 480 m vertical depth or 600 m down dip. The zone has an average true width of 12 m with a dip of approximately -60° to the north.

Figure 9.3 Zone 3 Oblique Long Section (not to scale)

9.5 ZONE 4

Zone 4 is located approximately immediately above the lower gabbro contact. At times, Zones 3 and 4 may actually merge into a single zone. It has been delineated by diamond drilling and is currently approximately 610 m in strike by 600 m vertical depth or 685 m down dip. The zone has an average true width of 21 m with a dip of approximately -60° to the north.

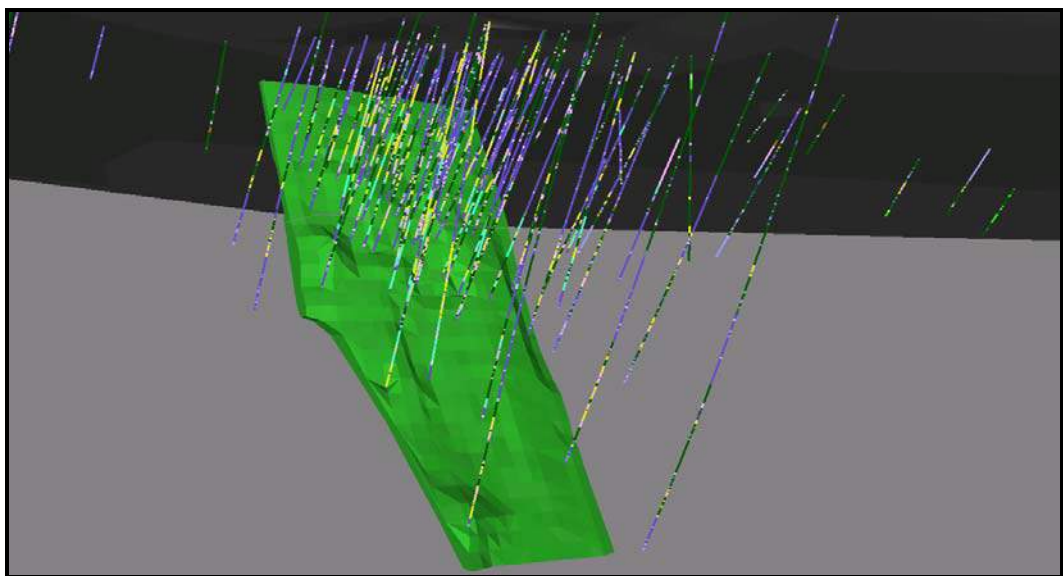

Figure 9.4 Zone 4 Oblique Long Section (not to scale)

9.6 ZONE 5

Zone 5 is located entirely within the footwall gabbro approximately 20 m from the contact with the metavolcanics that hosts the other four zones. Zone 5 has not been well defined as several drill holes do not completely pass through the zone. It has been delineated by diamond drilling and is currently approximately 350 m in strike by 670 m vertical depth or 760 m down dip. The zone has an average true width of 15 m with a dip of approximately -60° to the north.

Figure 9.5 Zone 5 Oblique Long Section (not to scale)

10.0 EXPLORATION

Neither Alto nor PFN has conducted any exploration activities other than the diamond drilling program detailed in Section 11.0 of this report.

11.0 DRILLING

A total of 152 drillholes totalling 45,149 m have been completed within the boundary of the property (Table 11.1). Approximately 66% of the meters drilling on the property have targeted the DAC deposit of which more than 50% have been drilled by Alto.

Table 11.1 Diamond Drill Summary

Program	Date	Holes	Meters
Soquem	1977-1979	9	1,232
Umex	1986	5	920
Cameco	1998-2001	63	20,623
Alto	2005-2008	56	14,746
Alto & PFN	2009-2010	19	7,628
Total		152	45,149

11.1 HISTORICAL DRILLING

A considerable amount of surface drilling was completed on the Project by various operators since the mid-1970'. Drill logs, assay summaries and assay certificates for most of these historic drillholes are available and were compiled into digital format to support the Mineral Resource estimate. The extent of this work is described in Section 6 "History". The procedures for various historical drilling campaigns have not been reviewed by Wardrop.

11.2 CAMECO 1998-2001 AND ALTO 2005-2008 DRILL CAMPAIGNS

Cameco was the first operator to start drilling the property in earnest. M. Koziol, Alto's President, has been involved on the project during the entire time that Cameco and Alto have operated the project and the diamond drill procedures have been consistent throughout this time period.

When Alto took over the project, a re-logging program was initiated, focusing on alteration and structural features, which were incorporated into a logging program. Data collected during Alto's core logging programs was entered directly on a lap top computer, utilizing the DHLogger program, developed by Century Systems. All sample intervals were selected and marked by the project geologist and then recorded in assay booklets.

A complete description of the Cameco procedure is available in the 2007 report by Habuchuck

11.3 ALTO & PFN 2009-2010 DRILL CAMPAIGN

The drilling conducted by Alto and PFN during the 2009-2010 drilling campaign was designed to:

- to fill-in large (50-75 m) gaps left untested on the DAC gold deposit between past drill intercepts above the -300 m level, to obtain additional geological and assay data in order to update the NI 43-101 compliant resource estimate
- to better define the eastern and western limits of the DAC deposit
- to test deeper levels below the DAC deposit
- to test the western projection of the DAC deformation zone.

Drilling was completed by Forage Mercier Inc based in Val d'Or, Quebec using a single LM-75 surface drill rig. A total of 19 new holes were drilled by Alto and PFN during the 2009-2010 winter drilling campaign of which 16 targeted the DAC deposit (Table 11.2). All holes were drilled NQ and all drill runs were 3.04 m in length.

11.3.1 DRILL COLLAR

Procedures for surveying diamond drillhole collars have been consistent between drilling programs. The Cameco-Alto grid was established by Cameco in 1997 and has been used to provide reference for surface geophysical surveys and diamond drill programs. The baseline for the cartesian grid is located approximately 750 m north of Highway 397 and oriented at an azimuth of approximately 270°. The baseline origin was set at 4+00 Northing and line 0+00 Easting.

In 2000, Corriveau and Associates carried out a GPS Trimble survey locating drillhole collars and grid lines. The drillhole collars were referenced to a UTM coordinate system using the NAD 83 projection with the baseline origin coordinates converted to 5401650N/317800E. The collar locations for the 2009-2010 surface drill programs was determined by chaining from surveyed drillhole casings and measurements with a chain from picket locations on cut grid lines.

The azimuth for the drill holes was determined by turning off angles from cut grids with a compass or by establishing foresight and back sight azimuths using pickets on cut lines.

11.3.2 DOWN HOLE SURVEY

Surveys were collected at approximately 50 m intervals using the Reflex E-Z shot.

11.3.3 CORE LOGGING

Core was logged by qualified geologists familiar with the project. Logging was conducted on laptop utilizing the DH Logger software from Century Systems. The core was logged at a rented facility near the Val d'Or airport with the core stored on racks at Forage Val d'Or compound in Val d'Or.

The drill logs recorded major lithological units, alteration, structure, mineralization, veining, textures and minor lithological units as well and the sample intervals.

11.3.4 DRILLHOLE CASING

The casing for all the drillholes with the exception of the first few holes completed by Cemeco are left in the ground and are capped with a marked casing cap to allow for easy location and identification (Figure 11.1).

Figure 11.1 Diamond Drillhole Cap

11.3.5 2009-2010 DIAMOND DRILL RESULTS

Drilling continued to establish continuity between past mineralized intercepts on the deposit. At shallow to moderate depths, drilling encountered moderate to high grade gold mineralization in most of the holes drilled last winter. Low-grade gold mineralization ranging 0.5 to 1.5 g/t was encountered over wide intersections in many of the holes ranging 8 to 25 m in length. In some holes, multiple wide low-grade zones were cored (Table 11.2).

Figure 11.2 Diamond Drill Results

Year	BHID	From (m)	To (m)	Length (m)	Au (g/t)	Zone

12.0 SAMPLING METHOD AND APPROACH

The following description of the sampling methodology was provided by Robert Tremblay, the geologist present during the drilling program. Drilling was not underway when Wardrop conducted the site visit. Field observations made during the site visit conclude that the logging and sampling methodology describe by Mr. Tremblay are to industry standards, and are acceptable to support a resource estimate.

- Core was delivered daily to the rented core logging facility by either Mr. Martin Genest, the owner of the logging facility, or by staff employed by Alto. Both parties also provided labour for sawing the core samples.
- Core lids are removed and the boxes placed on the core logging table in order.
- A geologist measures run lengths to confirm block markers.
- Core is photographed.
- Logging is completed by the geologist directly into a lap top computer using Century System's DH Logger.
- Sample lengths are variable, 20 cm minimum sample length, 2 m maximum sample length.
- The samples do not cross lithological boundaries.
- Quartz veins are isolated if possible as well as zones in increased sulphides or alteration.
- Sample intervals are transferred to a sample booklet with pre-printed sample numbers.
- Top-mounted core saw with a fresh water source was used to cut the core.
- The technician verifies the sample number from the drill log with the sample number from pre-printed sample books.
- The technician cuts the core and places one half in a plastic sample bag and returns the other half to the core box.
- One sample tag is placed in the sample bag; one sample tag is stapled into the core box at the beginning of the sample interval.
- Sample bags with sample and sample tag are sealed with zip ties.
- QA/QC samples are inserted into the sample stream (see Section 13.0 Sample Preparation, Analyses and Security for details).

- Samples are placed in rice bags and stored in the core logging facility until shipment.
- Samples are picked up Manitoulin Transport for shipment to Accurassay Laboratories preparation facility in Sudbury.

Figures 12.1 and 12.2 display the core logging facility and the core cutting facility used on the DAC project.

Figure 12.1 Core Logging Facility

Figure 12.2 Core Cutting Facility

13.0 SAMPLE PREPARATION, ANALYSES, AND SECURITY

13.1.1 *SAMPLE PREPARATION*

After the sample bags were sealed in rice bags, the samples were stored in the core logging facility waiting shipment. The samples would be stored there with only the personnel appointed by Alto having access. When enough samples had accumulated, the samples would be picked up by Manitoulin Transport for shipment to Accurassay Laboratories preparation facility in Sudbury.

Accurassay is an accredited facility, conforming to requirements of CAN P-4E ISO/IEC 17025, and CAN-P-1579.

All samples are processed using both Jaw Crushers and Ring Mill Pulverizes. Samples received by the lab are processed using the following sample preparation packages:

- dry, crush (<5 kilograms (kg)) 90% -8 mesh (2 mm),
- split (500 grams (g))
- Pulverize to 90% -150 mesh (106 μ).

All sample pulps, including field-inserted Standards and Blanks, were then sent to Accurassay Laboratories in Thunder Bay, Ontario for assaying.

13.1.2 *SAMPLE ANALYSES*

The gold assay methodology used a standard Fire Assay with AA finish technique on a 30 g aliquot taken from the 500 g pulp. The laboratory prepared and analyzed a second 500 g pulp from the reject for those samples that indicated gold values of between 1 g/t and 5 g/t on the initial analysis. The gold assaying method on the re-split used a standard Fire Assay with Gravimetric finish technique on a 30 g aliquot. Pulp metallic assays were performed on all samples that returned greater than 5 g/t gold on the first assay. This method is often used to determine true gold grades of core characterized by the presence of native gold, which is commonly distributed in an erratic fashion.

Altogether, during the 2009-2010 drill campaign, a total of 2,347 core samples were sent in for gold analysis by fire assay (30 g) with a finish by atomic absorption.

At no time was an Alto employee or designate of the company involved in the preparation or analysis of the samples.

13.1.3 *ALTO QA/QC PROGRAM*

Alto's Quality Assurance/Quality Control (QA/QC) programs consisted of the insertion of Blanks, Standard Reference Material (SRM) samples into the sample stream at set intervals. Commercial gold standards of three different grades were inserted every 25 samples submitted for assay. These samples bear numbers ending with 00, 25, 50 and 75. A commercial blank was inserted every 50th sample intervals, in numbers ending with 33 and 83

Alto did not include any field duplicates in the QA/QC program. In addition to the field-inserted QA/QC program, the laboratories operate their own laboratory QA/QC system. The labs insert quality control materials, Blanks and duplicates on each analytical run.

The results of the various QA/QC samples are further examined below, yet it should be noted that in all three SRM, the mean values were lower than the accepted values. This may mean that the sample values are slightly underestimated.

13.1.4 *BLANK QA/QC*

A commercial blank sourced from CDN Laboratories of Vancouver was inserted into the sample stream every 50th samples with sample numbers ending with 33 and 83. A total of 49 blank samples were inserted during the drilling campaign which represents 2% of the sample database (Figure 13.1)

There was only one failure within in the Blank QA/QC data set, which was actually the first Blank inserted during the program. Although any failure during a QA/QC program should be investigated, the fact that the only failure was the first sample is not a major concern. The variance in the Blank sample results increased over the last eleven insertions. This should be monitored in the future.

Alto should continue to use a Blank in their QA/QC program, with two modifications:

1. Replace the commercial blank with a locally sourced rock or core. The purpose of the Blank QA/QC sample is to monitor the preparation laboratory crushing and pulverizing for cross contamination. A commercial blank is already crushed and pulverized.
2. Stagger the location of the Blank sample. The sample should be placed within or immediately following a high-grade interval in order to check for cross contamination.

Figure 13.1 Blank QA/QC Chart

13.1.5 LOW GRADE SRM (CM-5)

The low grade SRM CM-5 has an accepted value of 0.294 g/t with a between lab's 95th confidence of 0.046 g/t. The mean grade of the QA/QC samples submitted was 0.284 g/t, just slightly lower than the accepted value but within the confidence level set for between labs. There was only one failure within the QA/QC sample suite submitted (sample #830175). This failure should be examined further to determine the potential source of the error (Figure 13.2).

Overall, there is a lot of variance in the sample results at the beginning of the program, which is evident in the moving average chart. Eventually the lab gets this under control. Past the 10th sample, there is a slight upward trend in the results, likely due to drift in the analytical instruments.

Figure 13.2 CM-5 Process Performance Chart

13.1.6 AVERAGE GRADE SRM (GS-1E)

The average grade SRM GS-1E has an accepted value of 1.160 g/t with a between lab’s 95th confidence of 0.060 g/t. The mean grade of the QA/QC samples submitted was 1.116 g/t, just slightly lower than the accepted value but within the confidence level set for between labs. There were no failures recorded within the QA/QC sample suite submitted, yet two samples were excluded from the suite as being miss labelled (samples 683375 and 685600) and are likely to be CM-5 samples (Figure 13.3).

Overall, there is a lot of variance in the sample results throughout the campaign, which is evident in the moving range chart. The lab does not get the process under control during the entire campaign. As this is mean grade range for the DAC deposit, this degree of variance in the samples should be a concern and investigated with the lab to see if there is a solution.

Figure 13.3 GS-1E Process Performance Chart

13.1.7 HIGH GRADE SRM (GS-5E)

The average grade SRM GS-5E has an accepted value of 4.830 g/t with a between lab's 95th confidence of 0.37 g/t. The mean grade of the QA/QC samples submitted was 4.587 g/t, which is lower than the accepted value but just within the confidence level set for between labs. There were no failures recorded within the QA/QC sample suite submitted (Figure 13.4).

Overall, there is a lot of variance in the sample results throughout the campaign, which is evident in the moving range chart. The lab does not get the process under control during the entire campaign.

Figure 13.4 GS-5E Process Performance Chart

14.0 DATA VERIFICATION

Wardrop carried out an internal validation of the diamond drillholes data files against the original drillhole logs and assay certificates. The validation of the data files was completed on 15 of the 152 drillholes in the total database or 9.7% of the dataset. Data verification was completed on collar co-ordinates, end-of-hole depth, down-the-hole survey measurements, From and To intervals, measurements of assay sampling intervals, and gold grades. No errors were identified in the collar, survey or lithology files.

The Assay file contained 45 entries that were corrected, primarily due to minor calculation discrepancy in the averaging of the assays. This represents less than 0.3% errors within the entire assay dataset. Corrections were made to the data set only if the difference in the assays were greater than 0.1 g/t. Table 14.1 outlines the corrections that were made to the data. All assays entered as zeros (0) were converted to half the detection limit and were not considered to be errors in the data.

Table 14.1 Corrected Assays

BHID	Sample #	Old Assay (g/t)	Corrected Assay (g/t)	Reason

DES06-85	194192	167	190	corrected average

Note: all values quoted at 0 g/t were changed to 0.0025 g/t (half detection limit). Only averages with differences greater than 0.1 g/t were corrected. Column *Au_reject_assay_gpt* contained a mix of data stated in ppb and ppm.

The drillhole data was imported into the Datamine program, which has a routine that checks for duplicate intervals, overlapping intervals and intervals beyond the end of hole. The errors identified in the routine were checked against the original logs and corrected.

Wardrop confirmed the locations of five surface drillhole collars during the site visit. Wardrop collected the collar locations using a Garmin GPSmap 60Cx handheld GPS unit. Table 14.2 displays the results of the collar validation. The accepted error for the 60Cx GPS unit is typically +/- 5 m range. Three of the five holes had collar coordinates that differed by more than ten meters. This was primarily in the northern direction. Although the hand held GSP is not deemed to be truly accurate, it is recommended that Alto have all the collars locations resurveyed in order to verify the locations.

Table 14.2 Drill Collar Check

BHID	Alto Ventures			Wardrop			Difference
	Easting	Northing	Elevation	Easting	Northing	Elevation	
DES09-120	317560	5401838	302	317556	5401851	302	13.7

DES10-137	317605	5401830	303	317608	5401834	307	6.1

Six independent samples of mineralized split drill core (¼ core) were collected for check assaying representing different mineralization grade ranges. The samples were bagged, sealed on site and delivered to ALS Minerals (ALS) in Val d’Or. The samples were prepared in Val d’Or and the pulps were shipped by ALS to Vancouver, British Columbia for analysis.

ALS is accredited to international quality standards through the International Organization for Standardization /International Electrotechnical Commission (ISO/IEC) 17025 (ISO/IEC 17025 includes ISO 9001 and ISO 9002 specifications) with CAN-P-1579 (Mineral Analysis).

The six samples were analyzed for gold using analysis package Au-AA25 which is a fire assay with an AA finish. Five samples were re-analyzed for gold using analysis package AU-Grav21, which is a fire assay with Gravimetric finish. Any samples returning values greater than 1 ppm would be re-assayed with a gravimetric finish (Table 14.3).

Of the samples collected, two samples had results with greater than 50% absolute difference, including one sample that Alto assayed as 0.7 g/t and Wardrop average for the quarter core was 4.98 g/t.

The check samples confirm the presence of gold in the system and the erratic nature.

Table 14.3 Check Assays

15.0 ADJACENT PROPERTIES

There are no properties adjacent or in the immediate vicinity of the Destiny Property.

16.0 MINERAL PROCESSING AND METALLURGICAL TESTING

Neither Alto nor PFN have conducted any metallurgical testing on material from the DAC deposit.

17.0 MINERAL RESOURCE AND MINERAL RESERVE ESTIMATES

17.1 HUBACHECK 2007 RESOURCES ESTIMATE

Hubacheck employed the “vertical cross-section method” supported by geostatistical 3D block modelling to estimate the gold resources within the DAC Deposit (Hubacheck, 2007).

The DAC Deposit resource estimate was supported by 30 drill holes arrayed on a grid layout on 11 drill fence sections from 317280E to 317580E, containing 2,274 assays. The geological interpretation is based on 11 north-south cross-sections spaced at 25 m apart from 317280E to 317580E and one 50 m spaced section (317,280E to 317,580E) covering a strike length of 300 m along the mineralized trend. Level plans spaced at 25 m apart were used to check the geological interpretation.

Computer drafted cross-sections showing mineral zone outlines were provided by Alto. The composite control table has 102 mineralized intersections that have zone codes related to the 2A, 2B, 3A, 4A and 5A zones and 2C, 3B and 5B sub-zones.

Detailed drilling on the DAC deposit between sections 317,405E and 317,505E shows good continuity and is of sufficient density on five sections that the gold resource outlined in this region are classified as “Indicated”. At the 3.0 g/t Au cut-off grade, Hubacheck estimates that the Indicated Mineral Resources of the DAC deposit total 166,863 tonnes at an average grade of 6.88 g/t Au and contain 36,892 oz of gold, cutting all high assays to 75 g/t Au. Hubacheck estimates that the Inferred Mineral Resources total 444,753 tonnes at an average cut grade of 4.46 g/t Au and contain 63,839 oz of gold.

17.2 WARDROP 2010 RESOURCE ESTIMATE

17.2.1 DATABASE

Alto maintains all drillhole data in a Century Systems DHLogger database. The headers, survey, lithology, assays and numerous other tables were exported to CSV format then transferred to Wardrop. The CSV files were created on October 6th, 2010. The Project has been drilled by 152 drillholes. However, only drillholes within

the areas of interest and with exploration potential were included in the resource estimate.

All resource estimations were conducted using Datamine Studio 3 version 3.19.3638.0.

Table 17.1 summarizes the number of drillholes used in the resources estimate for each zone.

Table 17.1 Drill Data Set

	Project Total	Zone 1	Zone 2	Zone 3	Zone 4	Zone 5
# of Holes	152	68	65	52	65	47

17.2.2 SPECIFIC GRAVITY

A total of 49 samples were tested for Specific Gravity (**SG**) from eight drill holes coinciding with intervals used in the resource estimation process. A few of the SG determinations included boundary samples in alteration zones surrounding main veins. The Zone 2 veins had 39 determinations. Wardrop used a SG factor of 2.76 for the mineral resource estimate.

Wardrop would recommend that Alto continue to collect SG measurements from various rock types in order to build up the data set. At a minimum, 2% of the data set should have a SG measurement. This would mean that Alto's current SG data set should have a minimum of 115 samples.

17.2.3 EXPLORATORY DATA ANALYSIS

Assays

The five zones (1 through 5), which are part of the Mineral Resource, were sampled by a total of 5,818 assays (Table 17.2). Complete assay information was provided for gold.

Table 17.2 DDH Assay Statistics

Zone	Field	N samples	Min	Max	Mean	Stand Dev
Zone 1	LENGTH	954	0.10	26.00	1.15	1.67
	AU_GT	860	0.00	54.10	0.58	2.20
Zone 2	LENGTH	2046	0.05	22.00	1.00	1.29
	AU_GT	1983	0.00	190.00	1.01	5.41
Zone 3	LENGTH	964	0.05	24.80	1.09	1.39
	AU_GT	897	0.00	47.10	0.73	2.52
Zone 4	LENGTH	1621	0.01	11.20	1.00	0.75
	AU_GT	1532	0.00	38.20	0.53	1.86
Zone 5	LENGTH	782	0.01	30.10	1.51	2.58
	AU_GT	546	0.00	47.40	0.91	3.25

Grade Capping

Raw assay data was examined to assess the amount of metal that is at risk from high-grade assays. The Datamine© Decile function was used to determine if grade capping was required for gold in the various zones. Wardrop elected to apply a top cut to the grades that exceeded 40% metal content in the ninetieth (90th) decile. Various capping grades were applied to the zones based on the 99th percentile. Tables 17.3 shows a summary of the top cuts that were applied to the various zones datasets.

Table 17.3 Grade Capping

Zone	# Sample	# Samples Capped	Grade Range Capped	Capping Value	% Capped
1	341	5	8.32 - 54.13	7.53	1.5%
2	812	9	22.1 - 190	19.63	1.1%
3	371	9	6.92 - 47.1	6.66	2.4%
4	511	6	17.71 - 38.01	10.80	1.2%
5	187	8	16.19 - 58.9	14.00	4.3%

Composites

Gold assay data were composited into 1 m downhole intervals honouring the interpreted geological solids. A 1 m composite length was selected as a majority of the assays are in the 1 m range for length, and it corresponds to approximately a half to a third the cell size to be used in the modelling process. The backstitching process was used in the compositing routine to ensure all captured sample material was included. The backstitching routine adjusts the composite lengths for each individual drillhole in order to compensate for the last sample interval. The result is individual boreholes have composites that vary in length from 0.90 to 1.07 m, yet have a mean

composite length of 1 m. Table 17.4 summarizes the statistics of the boreholes after capping and compositing.

Table 17.4 DDH composite Stats

Zone	Field	N samples	Min	Max	Mean	Stand Dev
Zone 1	LENGTH	1099	0.94	1.07	1.00	0.020
	AU_GT	794	0.003	9.077	0.475	0.857

	AU_GT	486	0.003	17.650	0.691	1.707

17.2.4 GEOLOGICAL INTERPRETATION

Three-dimensional wireframe models of mineralization were developed for the five zones based on an Au cutoff of greater than 0.3 g/t and a minimum 2-m horizontal width. Bedrock subsurface was also created using a digital terrain model based on the data provided in the drill logs.

Sectional interpretations were digitized in Datamine Studio version 3.19.3638.0 software, and these interpretations were linked with tag strings and triangulated to build three dimensional solids. Table 17.5 tabulates the solids and associated volumes. The solids were validated in Datamine and no errors were found.

The zones of mineralization interpreted for each area were generally contiguous; however, due to the nature of the mineralization there are portions of the wireframe that have grades less than 0.3 g/t, yet are still within the mineralizing trend.

The non-assayed intervals were assigned void (-) value. The author believes that non-assayed material should not be assigned a zero value, as this does not reflect the true value of the material.

Table 17.5 Wireframe Statistics

Zone	Wireframe Dimensions						Volume (m ³)
	Minimum X	Maximum X	Minimum Y	Maximum Y	Minimum Z	Maximum Z	
1	317100	317622	5401575	5401921	-253	330	4,341,000.18
2	317181	317641	5401514	5401899	-285	321	7,685,900.28

4	317721	317721	5401441	5401845	-365	311	7,278,309.26
5	317269	317630	5401392	5401831	-400	312	6,698,055.69

17.2.5 SPATIAL ANALYSIS

Variography, using Datamine Studio version 3.19.3638.0 software, was completed for gold in all five zones individually. Downhole variograms were used to determine nugget effect and then correlograms were modelled to determine spatial continuity in the zones.

Table 17.6 summarizes results of the variography.

Table 17.6 Variography Results

VDESC	VREFNUM	VANGLE1	VANGLE2	VANGLE3	VAXIS1	VAXIS2	VAXIS3	NUGGET	ST1	ST1PAR1	ST1PAR2	ST1PAR3	ST1PAR4
Z1	1	0	0	45	3	2	1	0.3	1	80	60	10	0.437
Z2	2	0	0	45	3	2	1	0.01	1	40	30	10	0.9
Z3	3	0	0	45	3	2	1	0.02	1	90	40	10	0.8
Z4	4	0	0	45	3	2	1	0.25	1	40	30	10	0.75
Z5	5	0	0	45	3	2	1	0.1	1	50	70	10	0.9

17.2.6 RESOURCE BLOCK MODEL

Individual block models were established in Datamine for all five zones using one parent model as the origin. The model was not rotated.

Drillhole spacing varies with the majority of the drilling tightly spaced from 25 m. A block size of 5 x 2 x 5 m was selected in order to accommodate the more closely spaced drilling and the narrow nature of the mineralization.

Subcelling of the block model on a 1 x 1 x 1 allows the parent block to be split once in each direction to more accurately fill the volume of the wireframes, thus more accurately estimate the tonnes in the resource.

Table 17.7 summarizes details of the parent block model.

Table 17.7 Parent Block Model

Origin			Cell Size			Number of Cells		
X Origin	Y Origin	Z Origin	XINC	YINC	ZINC	NX	NY	NZ
317000	5401300	-500	5	2	5	160	350	180

The interpolations of the five zones were completed using the estimation methods: nearest neighbour (NN), inverse distance squared (ID2) and ordinary kriging (OK). The estimations were designed for three passes. In each pass a minimum and maximum number of samples were required as well as a maximum number of samples from a borehole in order to satisfy the estimation criteria. Table 17.8 and 17.9 summarizes the interpolation criteria for all five zones.

17.2.7 RESOURCE CLASSIFICATION

Several factors are considered in the definition of a resource classification:

- National Instrument 43-101 requirements
- Canadian Institute of Mining, Metallurgy and Petroleum guidelines.
- Authors experience with Archean and Proterozoic gold deposits.
- Spatial continuity based on variography of the assays within the drillholes.

No environmental, permitting, legal, title, taxation, socio-economic, marketing or other relevant issues are known to the authors that may affect the estimate of mineral resources. Mineral reserves can only be estimated on the basis of an economic evaluation that is used in a Preliminary Feasibility Study or a Feasibility Study of a mineral project; thus, no reserves have been estimated. As per NI 43-101, mineral resources, which are not mineral reserves, do not have to demonstrate economic viability.

17.2.8 MINERAL RESOURCE TABULATION

The resource reported as of January 2011 has been tabulated in terms of a gold cutoff grade. The Mineral Resources for the five zones at the DAC deposit are tabulated in Tables 17.10 to 17.15 for the Indicated and Inferred resources respectively. The resources are tabulated using various cutoff grades for gold up to an upper bound of greater than 3.0 g/t gold.

Table 17.10 Zone 1 Tonnes & Grades

Based on the results of similar gold projects located in the provinces of Ontario and Quebec, a 0.5g/t Au cutoff was used to tabulate the total within the various categories. This based on the following parameters;

- 4:1 stripping ratio
- Operating cost of \$14.30/tonnes at 10,000 tpd
- Gold price of \$US973/troy oz
- \$US to \$Cdn conversion of 1.02
- Gold Recovery of 94%

Table 17.16 summaries the resource estimate at the 0.5 g/t Au cutoff.

Table 17.16 DAC Resource Estimation

Class	Zone	Tonnes	Au(g/t)	Au Ounces
Indicated	1	1,395,600	0.84	37,760
	2	2,942,700	1.19	112,640
	3	1,370,700	0.99	43,680
	4	3,542,600	1.06	121,220
	5	1,573,900	0.97	49,230
	Total	10,825,500	1.05	364,530
Inferred	1	971,900	0.70	21,720
	2	1,841,100	1.06	62,490
	3	725,500	0.93	21,760
	4	3,085,300	0.89	88,770
	5	1,706,600	0.96	52,850
	Total	8,330,400	0.92	247,590

Note: ID2 method @ 0.5 g/t cut-off

17.2.9 VALIDATION

The DAC Deposit gold grade models were validated by two methods:

1. Visual comparison of colour-coded block model grades with composite grades on section and plan.
2. Comparison of the global mean block grades for ordinary kriging, inverse distance squared, nearest neighbour and composites.

Visual Comparison

The visual comparisons of block model grades with composite grades for each of the five zones show a reasonable correlation between the values. No significant discrepancies were apparent from the sections and plans reviewed, yet grade smoothing is apparent (Figures 17.1 and 17.2).

Figure 17.1 Cross Section

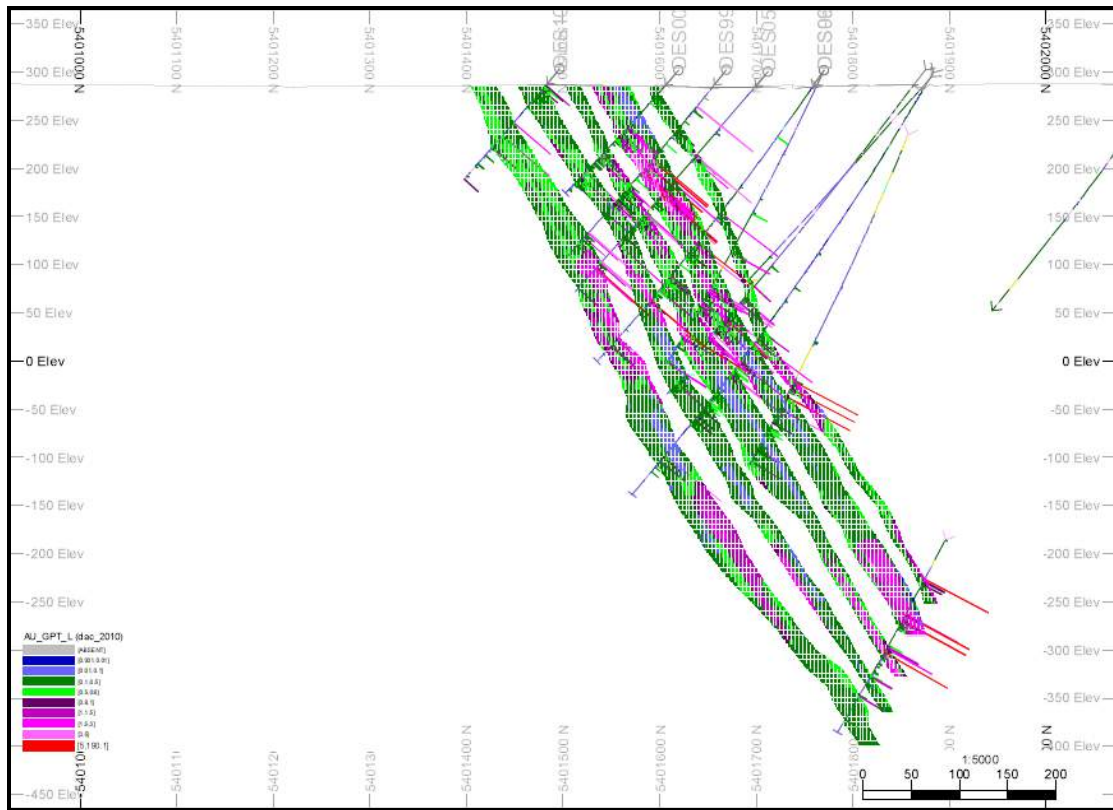

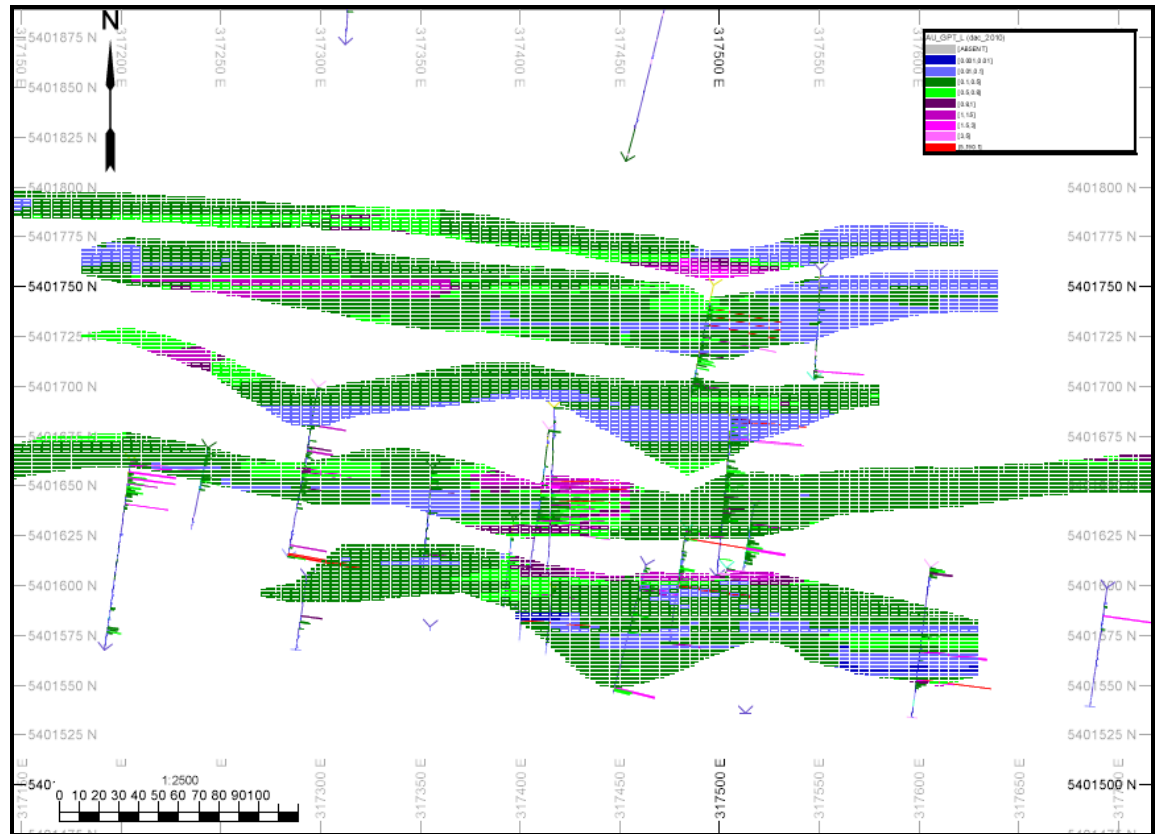

Figure 17.2 Plan View

Global Comparison

The global block model statistics for the ordinary kriging model were compared to the global inverse distance squared and nearest neighbour model values as well as the composite capped drillhole data. Table 17.17 shows this comparison of the global estimates for the three estimation method calculations. In general, there is agreement between the ordinary kriging model and inverse distance squared model and nearest neighbour model. Larger discrepancies are reflected as a result of lower drill density in some portions of the model. There is a degree of smoothing apparent when compared to the diamond drill statistics. Comparisons were made using all blocks at a 0 g/t cutoff.

Table 17.17 Global Mean Statistics

	DDH Capped Composite	NN Tonnes	NN Grade	ID2 Tonnes	ID2 Grade	OK Tonnes	OK Grade
Zone 1	0.48	8,883,000	0.43	8,883,000	0.41	8,883,000	0.43
Zone 2	0.68	17,963,000	0.43	17,963,000	0.46	17,963,000	0.47
Zone 3	0.54	7,479,000	0.40	7,479,000	0.44	7,479,000	0.44
Zone 4	0.44	15,877,000	0.47	15,877,000	0.58	15,877,000	0.56
Zone 5	0.69	16,281,000	0.38	16,281,000	0.38	16,281,000	0.39

17.3 2010 MODEL COMPARED TO 2007 MODEL

There are several parameters that differentiate the 2010 Wardrop block model and the 2007 Hubacheck block model. The primary differences are listed in table 17.18.

Table 17.18 Model Parameter Differences

	2010 Wardrop Model	2007 Hubacheck Model
Number of Drill Holes	68	30
Grade Capping	variable by zone	yes - set at 75 g/t
Composite Length	1.0 m	2.0 m
Gold Pricing	\$US973/oz	\$US530/oz
Cut off Grade	0.5 g/t	3.0 g/t
Number of Mineral Zones	5 zones	5 main zones with 8 sub-zones
Estimation Method	Inverse distance with nearest neighbour and krig validation	cross section nearest neighbour with inverse distance validation

There has been a substantial amount of new drilling completed since the Hubacheck model was created with the intention of increasing the size of the mineral resource. In addition, the different modeling parameters, would lead to a change in the resource tonnes being stated.

When similar cut off grade parameters used in the 2007 Hubacheck model are applied against the 2010 Wardrop nearest neighbour model, comparable grades are registered (Table 17.19).

Table 17.19 Comparable Grades

	2010 Wardrop NN Model		2007 Hubacheck Cross Section		Difference		% change	
	Tonnes	Grade (g/t)	Tonnes	Grade (g/t)	Tonnes	Grade (g/t)	Tonnes	Grade
Indicated Resource @ 3.0 g/t cutoff	930,400	6.16	166,863	6.88	763,537	-0.72	458%	-10.47%
Inferred Resources @ 2.0 g/t cutoff	708,800	4.43	444,753	4.46	264,047	-0.03	59%	-1%

This would indicate that 1) the 2007 Hubacheck model was valid at the time it was created. 2) The additional drill holes placed into the deposit, while expanding the resource, the grades intersected remain consistent with the grades reported in earlier drill programs. Although the grades are variable within drillholes, the grades have a lower variability within the entire zone. This would lead to the understanding that there is little potential to identify a higher grade core within the deposit.

Going forward, all future resources estimate on the DAC Deposit should be completed using the Inverse Distance or Krig methodology with the Nearest Neighbour method only being used to compare the global results for validation purposes.

18.0 OTHER RELEVANT DATA AND INFORMATION

There is no other relevant data or information material to the project.

19.0 INTERPRETATION AND CONCLUSIONS

Based on the review of the available information and observations made during the site visit, the author concludes the following, in no particular order of perceived importance:

- The DAC Deposit is currently held 100% by Alto, which has entered into a business arrangement with PFN whereby PFN has an option to earn 60% of the project from Alto.
- The DAC is analogous to the shear-hosted quartz-carbonate vein lode gold typical to the Abitibi Belt of eastern Ontario and western Quebec.
- The DAC is associated with sheared quartz-porphyritic felsic intrusive sills with mylonitic deformation, biotite and sericitic (potassic) alteration and locally, silica alteration.
- Mineralization is currently defined in five parallel zones.
- Drilling and sampling procedures, sample preparation and assay protocols are generally conducted in agreement with best practices.
- Verification of the drillhole collars, surveys, assays, core and drillhole logs indicates the Alto data is reliable.
- Based on the QA/QC program, the data is sufficiently reliable to support the resource estimate generated for the five zones at the DAC Deposit.
- The mineral models have been constructed in conformance to industry standard practices.
- The geological understanding is sufficient to support the resource estimation.
- At a gold cut-off grade of 0.5 g/t Au, the five zones contain an Indicated Resource of about 10.8 million tonnes with an average grade of 1.05 g/t Au. The Inferred Resource totals 8.3 million tonnes with an average grade 0.92 g/t Au.
- The specific gravity value used to determine that tonnage was derived from limited samples, which may reflect a lack of precision with respect to the resource tonnages.
- The DAC resource remains open in both strike and dip.
- The property hosts other zones with similar geology, alteration and mineralization to the DAC deposit.

20.0 RECOMMENDATIONS

It is the author's opinion that additional exploration expenditures are warranted. Two separate exploration programs are proposed. Each can be carried out concurrently and independently of each other, and neither is contingent on the results of the other.

20.1 PHASE 1 DAC RESOURCE EXPANSIONS

Phase 1 is designed to investigate the strike extension of the current resource for Zones 1, 2, 3, 4 and 5. This will entail a diamond drilling program.

The drilling campaigns should be designed to target the potential strike extensions of Zones 1 to 5 to a depth of approximately 450 m vertical. Some holes will have to be collared in to Zone 1 in order to intersect Zone 5 at a shallow depth.

Upon the completion of the drilling campaign, all drill collars completed since 2000 should be surveyed and the drill database updated.

Table 20.1 summarizes the exploration program proposed.

Table 20.1 Phase 1

Project	Activity	Rate	Units	Cost
DAC	DD Drilling (13 holes)	\$150/m*	6,000	\$900,000
DAC	Survey Collars	\$350/day	3	\$24,000
Indirect Costs	Salaries	\$8000/month	4	\$32,000
	Fuel	\$1500/month	3	\$4,500
	Admin - Camp	\$2500/month	3	\$7,500
	Consumable			\$55,000
Total				\$1,023,000

*Note: includes all drilling related charges, sample analysis, road building.

20.2 PHASE 1 DAC RESOURCE DELINEATION

Phase 2 is designed to investigate the known resource in order to improve the understanding of the geometry and potentially increase the resource category of all five zones. The Phase 2 program does not depend on the successful results from the Phase 1 program.

Drilling should target all zones on an approximate grid of 20 m along strike and 15 m down dip.

Table 20.2 summarizes the Phase 2 exploration budget proposed.

Table 20.2 Phase 2

Project	Activity	Rate	Units	Cost
DAC	DD Drilling (45holes)	\$150/m*	20,000	\$3,000,000
Indirect Costs	Salaries	\$8000/month	7	\$56,000
	Fuel	\$1500/month	5	\$7,500
	Admin - Camp	\$2500/month	5	\$12,500
	Consumable			\$100,000
Total				\$3,176,000

*Note: includes all drilling related charges, sample analysis, road building.
